

Data Observations

Key observations from the communication-log and campaign data that affect how the metric should be interpreted.

1. Communication records can exist before a campaign is officially reportable

Campaign 9004 already has successful communication-log records, but its creation status is still **approval_awaiting**. This means the presence of a send record alone is not enough to include it in the Finance metric. The campaign status also has to be checked.

2. Retry campaigns are linked through the campaign hierarchy

The data contains multi-level retry chains such as **9001 -> 9002 -> 9003**. These are not three independent communications. They represent repeated attempts for the same underlying communication, which is why customers are deduplicated within a retry family.

3. A failed send does not automatically disappear from the story

A customer can fail on one campaign and later succeed through a retry. For example, a customer may fail on 9001 and then be successfully delivered on 9002 or 9003. The earlier failed attempts should not be counted, while the customer is counted once when the retry family is evaluated.

4. A global COUNT(DISTINCT customer_id) would be misleading

The combination of retry-family deduplication and standalone-event counting means there is no single counting rule that can be applied to every row. Using DISTINCT across the entire dataset would undercount the legitimate repeated C20 send in campaign 9101.

Final observation: The main lesson from the dataset is that a communication-log row is not automatically a qualifying send. Reporting eligibility, delivery outcome, retry relationships, and standalone-campaign behavior all need to be considered before arriving at the Finance number of **22**.
